

Exploring Control Strategies in ATC: Implications for Complexity Metrics

*Jonathan Histon &
Prof. R. John Hansman*

*JUP Meeting,
June 21-22, 2001.*

Introduction

- **Project Goal**
 - ❑ Develop operationally useful measures of complexity.
- **Why study complexity?**
 - ❑ Cognitive challenge of ATC is one of the fundamental limits that restricts the capacity of a piece of airspace.
 - ❑ Previous research has concentrated on measures of that cognitive challenge in the Free Flight environment.
 - ◆ E.g. “Dynamic Density”
 - ❑ However, these measures do not take into account the inherent structure present in the current operational environment.
- **Incorporating structure would:**
 - ❑ Increase the sophistication of predictions of potential controller overload situations (E.g. Monitor Alert in ETMS).
 - ❑ Provide guidance to airspace redesign projects.

Our Approach

- **Collaborative effort, sponsored by FAA, with partners at Centre d'Etudes de la Navigation Aérienne (CENA) in France.**
- **Step 1 - Literature Review**
 - ❑ Current metrics
 - ◆ Simple count of Number of Aircraft in a Sector
 - ❑ Previously proposed metrics
 - ◆ NASA's Dynamic density, Wyndemere Corporation
- **Step 2 - Field Observations**
 - ❑ Case study at Boston TRACON
 - ◆ Comparison of sectors – what makes one harder than another?
 - ❑ Visits, interviews at Boston Center, Montreal Center
 - ❑ Generated preliminary list of key factors in complexity.
 - ❑ "Flight Explorer" and Analysis of Current System Operation
- **Step 3 - Proposing metrics**
- **Step 4 - Validating those metrics**

System Response to Complexity

- **Why study structure in the current system?**
 - ❑ The ATC system is an adaptive system.
 - ◆ Biological analogy.
 - ❑ Evolve in response to controller capability limits being exceeded
 - ◆ E.g. splitting sectors, changing procedures
 - ❑ Therefore, observing the current system can provide insight into complexity limits
 - ◆ Use of Structure
 - ◆ Maximum observed complexity in sectors.

“Flight Explorer”

- **Capabilities:**

- ☐ ETMS feed in real-time on desktop PC
- ☐ IFR flights in United States, Canada, and United Kingdom.
- ☐ For each flight:
 - ◆ Present position, Altitude, Speed vector
 - ◆ Historical radar track
 - ◆ Current flight plan
- ☐ Displays:
 - ◆ Weather images
 - ◆ Sector boundaries
 - ◆ Airways, Nav aids etc...

- **Technical details:**

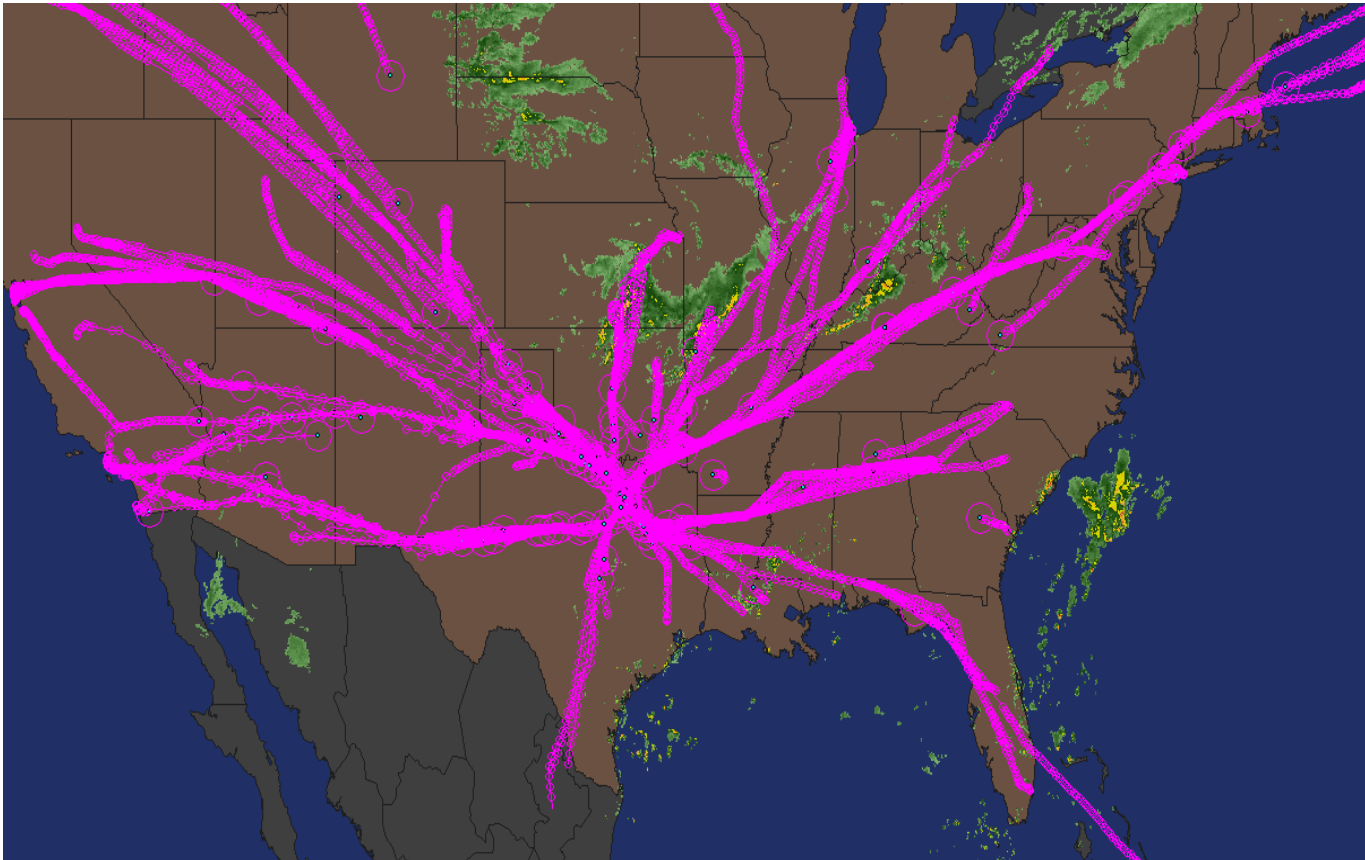

- ☐ Commercial service provided by Flight Dimensions International
(www.flightexplorer.com)
- ☐ Update rate ~ 1 minute

Preliminary Observations

Dallas Fort-Worth

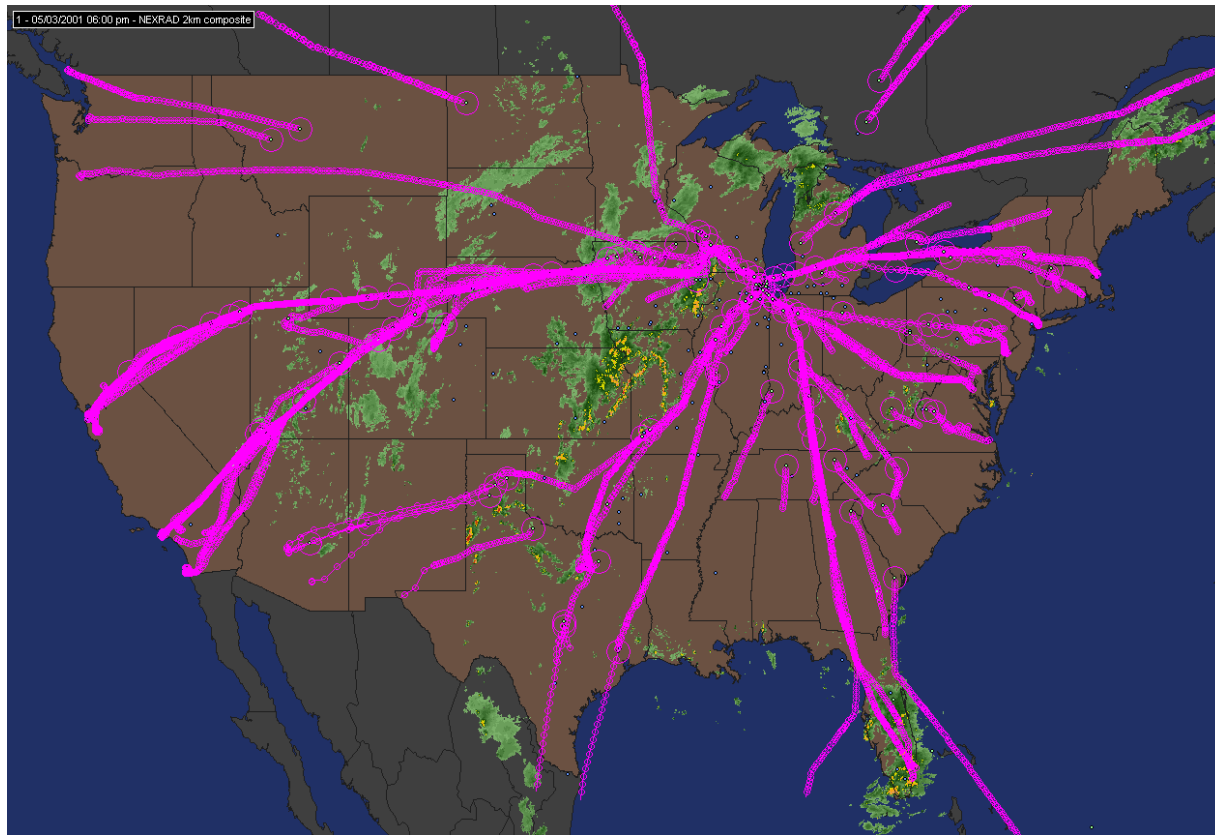

- Aircraft are condensed into distinct flows feeding 4 arrival fixes.

- June 20, 2001 12:19 p.m. 153 Aircraft In-bound

Chicago

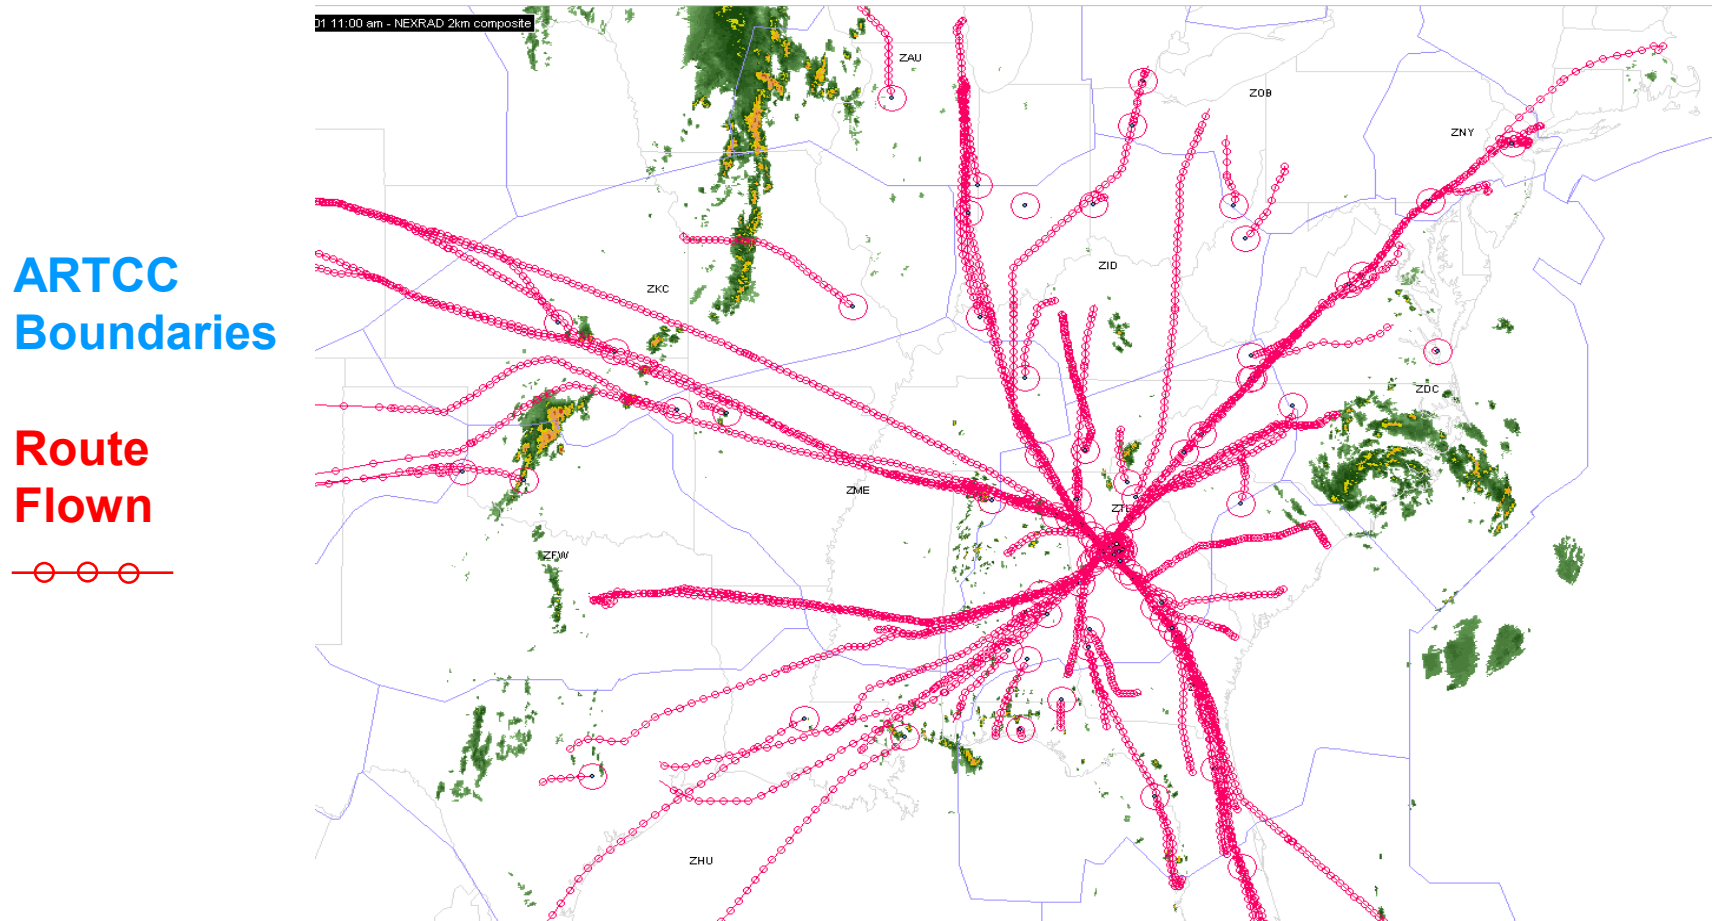

- Presence of branching structure consolidates aircraft into flows, reducing the complexity of the ultimate merging process

- May 3, 2001 6:20 p.m. 295 Aircraft In-bound

Atlanta

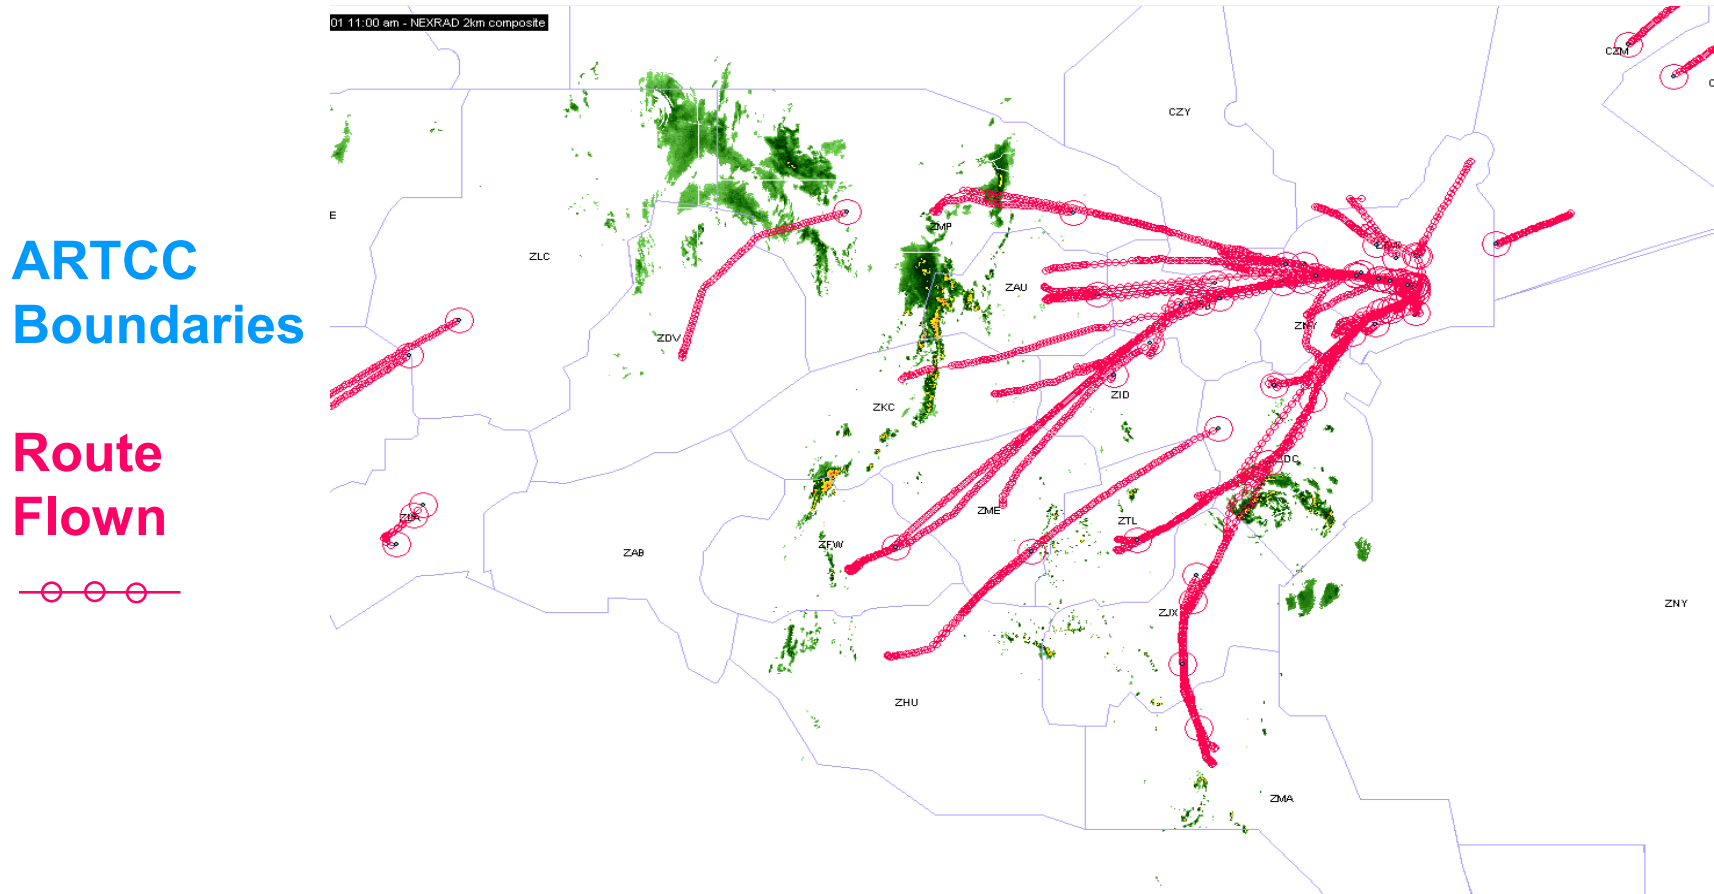

- Condensation and merges have reduced 116 trajectories at airport to 4

- June 14, 2001 11:15 a.m. 116 Aircraft In-bound

Boston

- Similar branching pattern is observed

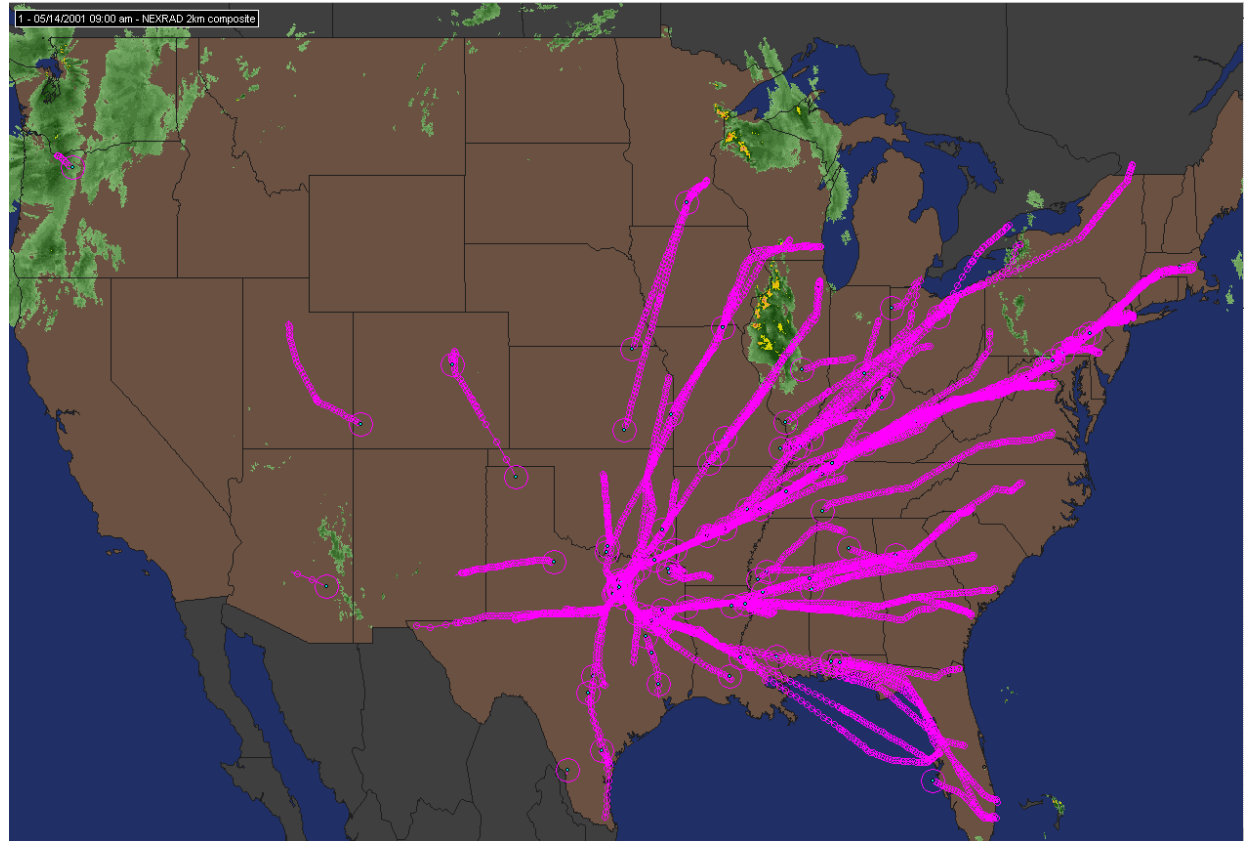

- June 14, 2001 11:21 a.m. 78 Aircraft In-bound

Dallas

- Complexity is increased by need to handle large groups of aircraft in a short time.

ARTCC
Boundaries

Route
Flow

- May 14, 2001 9:18 a.m. 117 Aircraft In-bound

San Francisco

- Special use airspace provides additional constraints

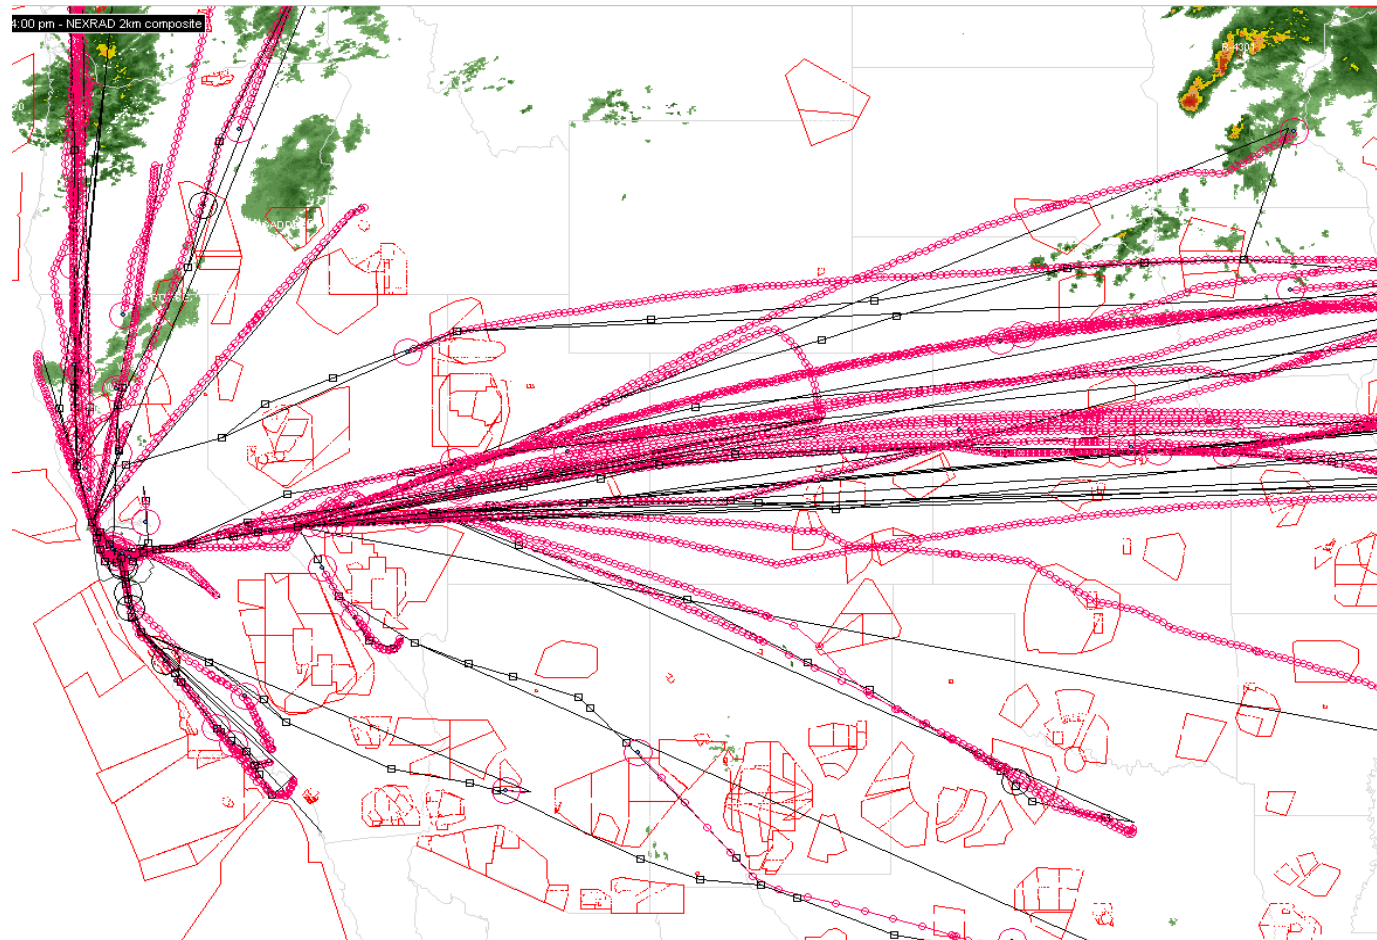

**Special Use
Airspace**

**ARTCC
Boundaries**

**Route
Flown**

Flight Plan

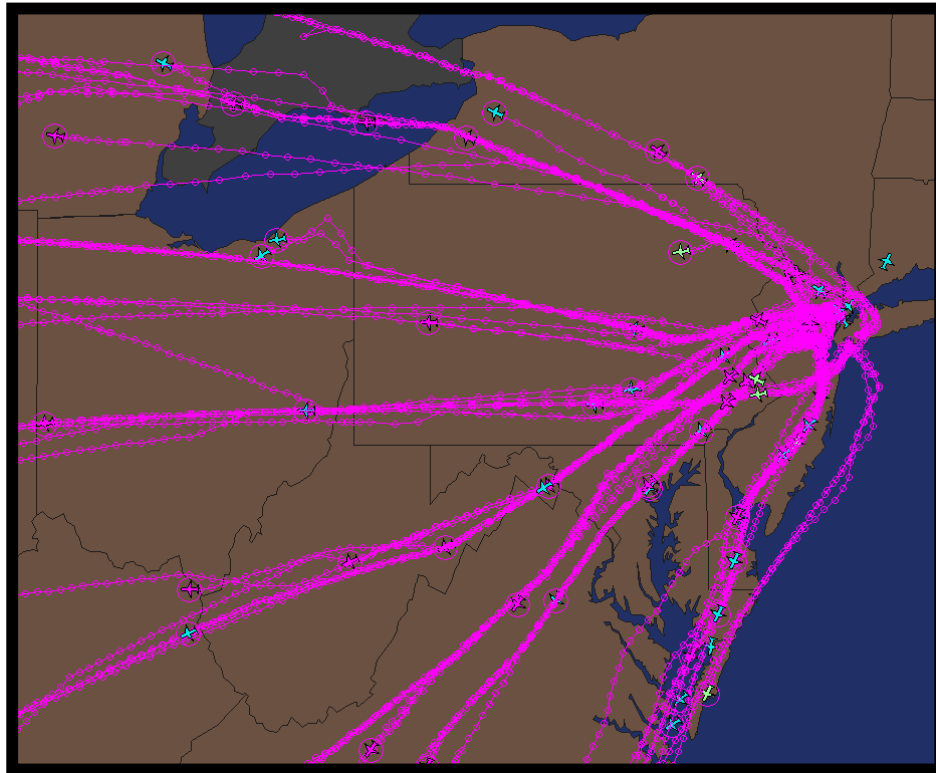

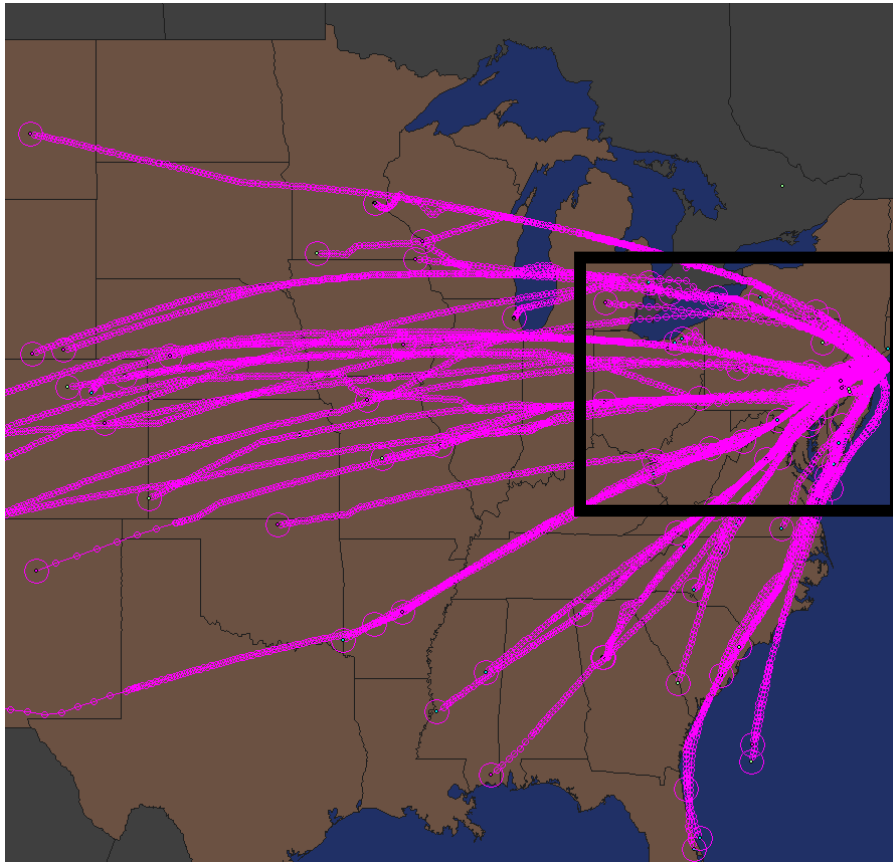

- June 11, 2001

4:13 p.m.

78 Aircraft In-bound

New York City (LGA, EWR, JFK)

- Departures can be structured as well:

• April 30, 2001 2:40 p.m.

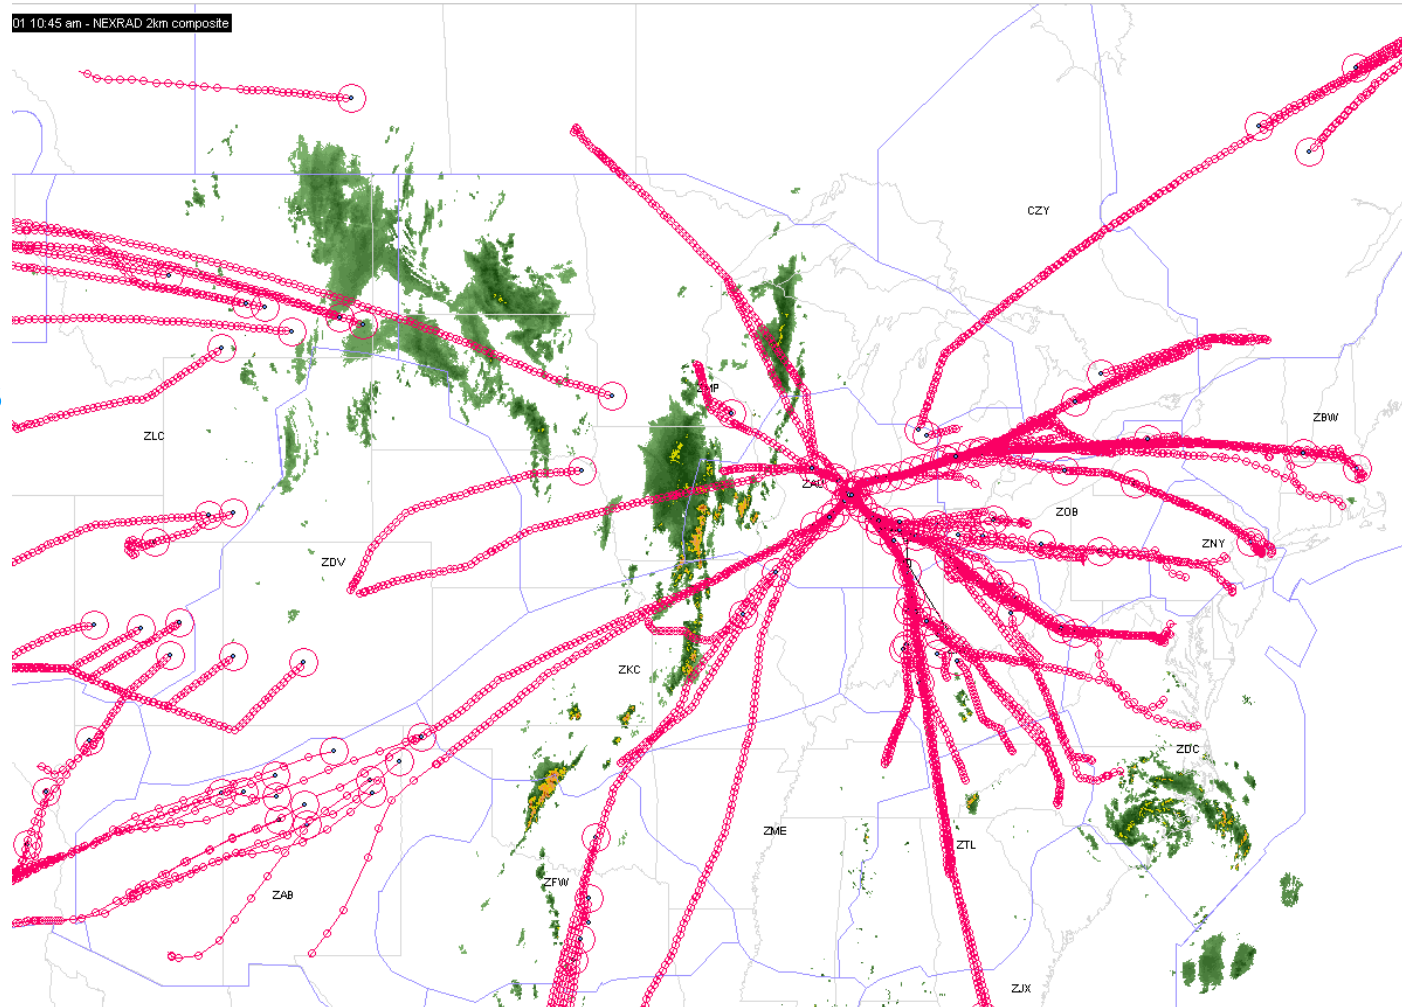

135 Aircraft Out-bound

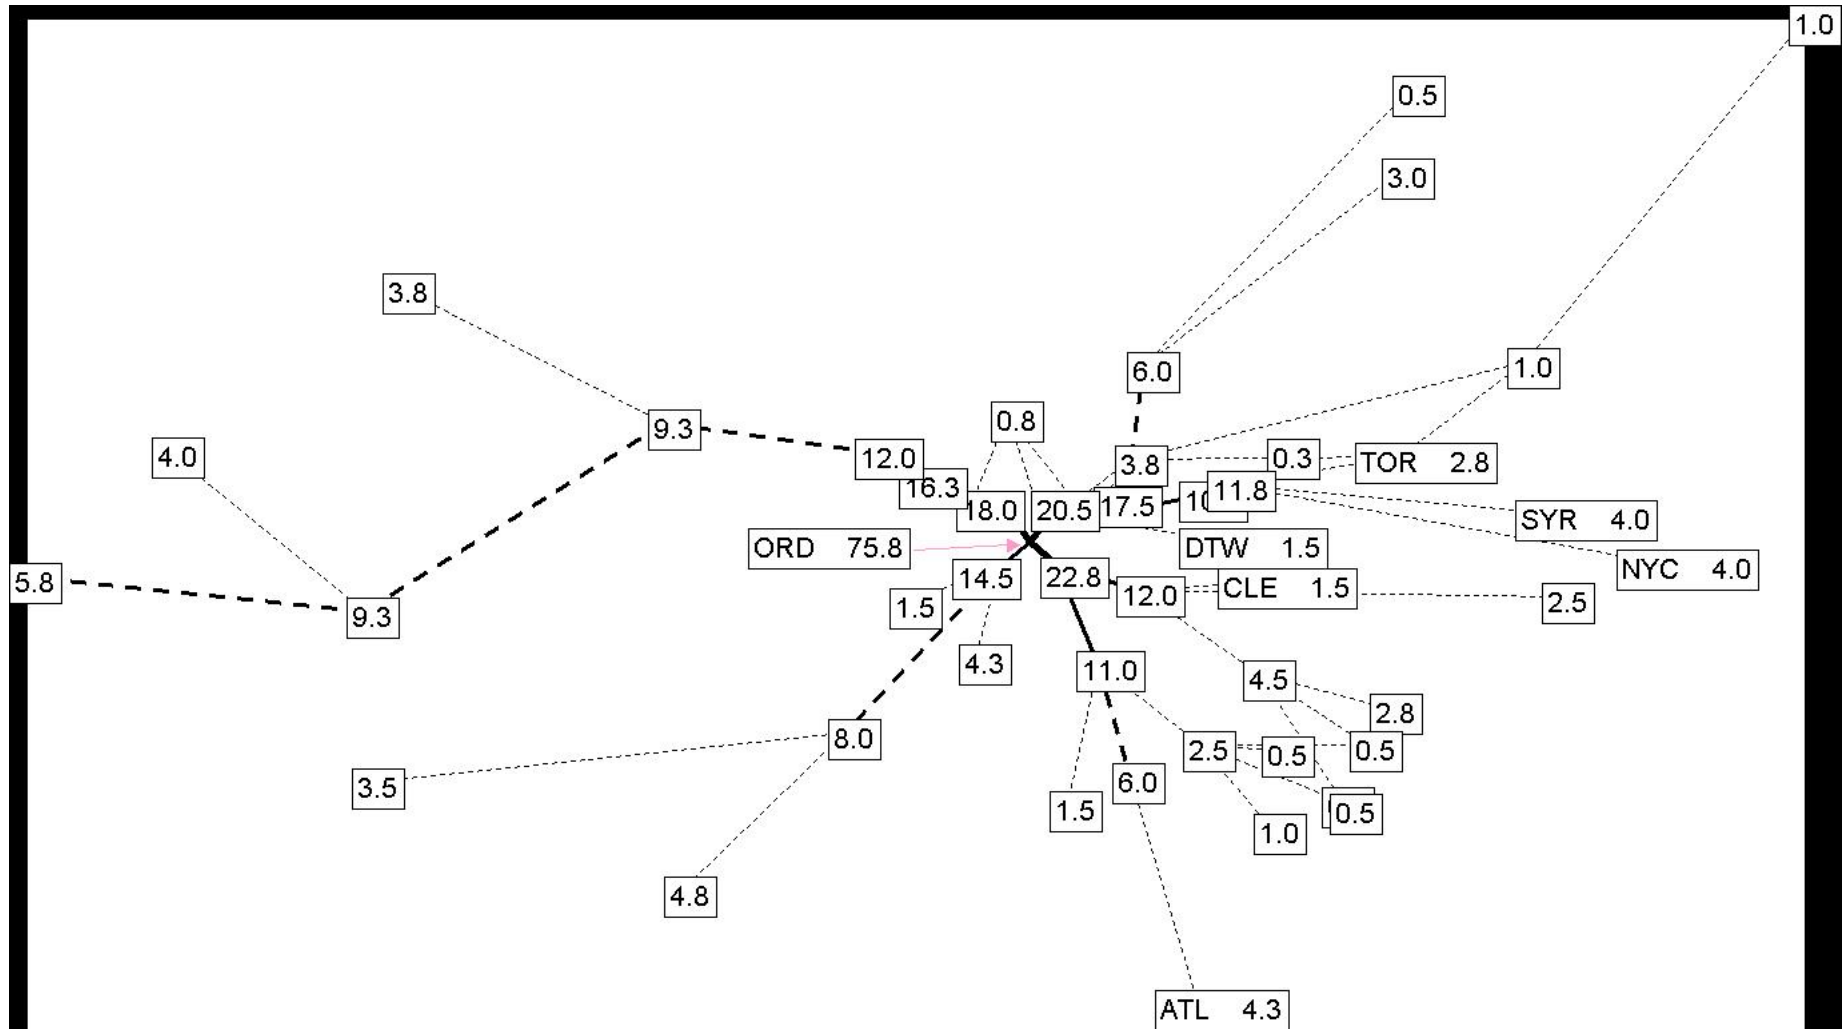

Chicago

- June 14, 2001 11:04 a.m. 160 Aircraft In-bound

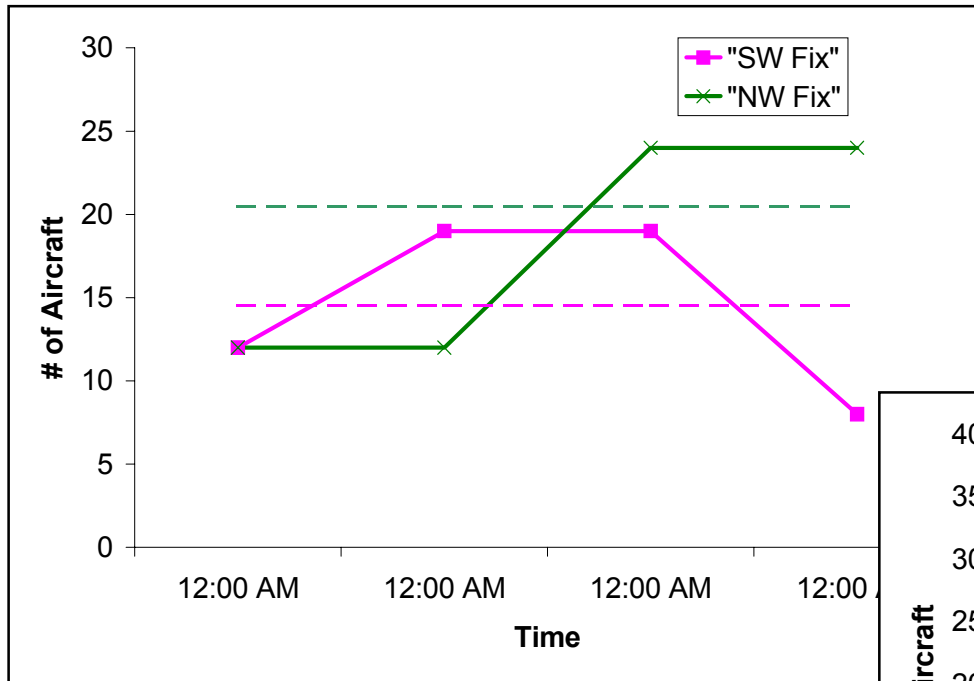

ARTCC
Boundaries

Route
Flow

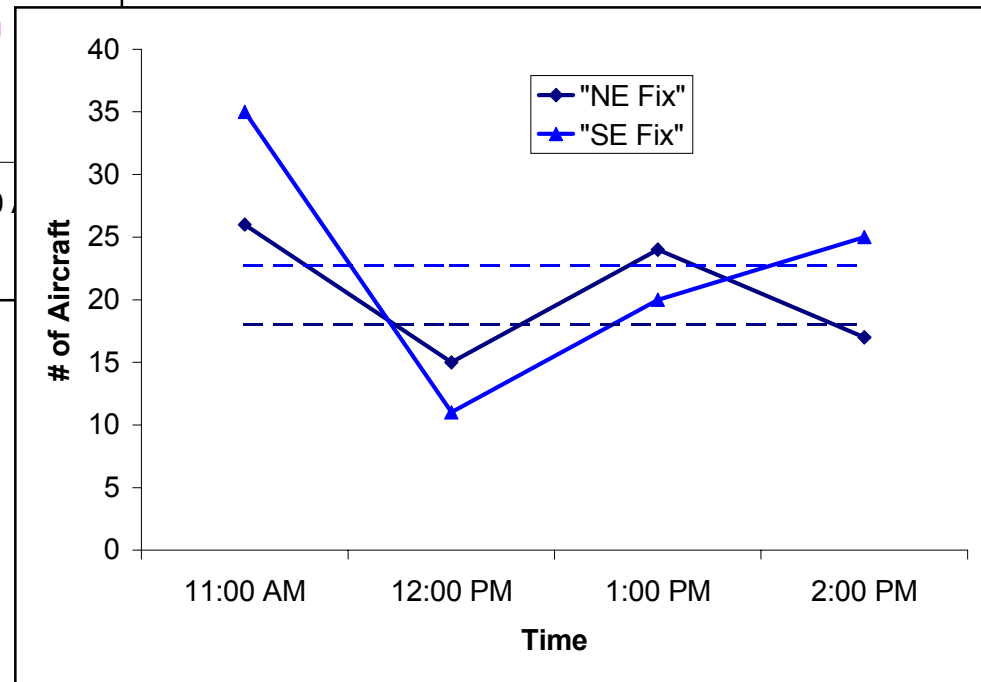

Temporal Variations in Demand

East Fixes

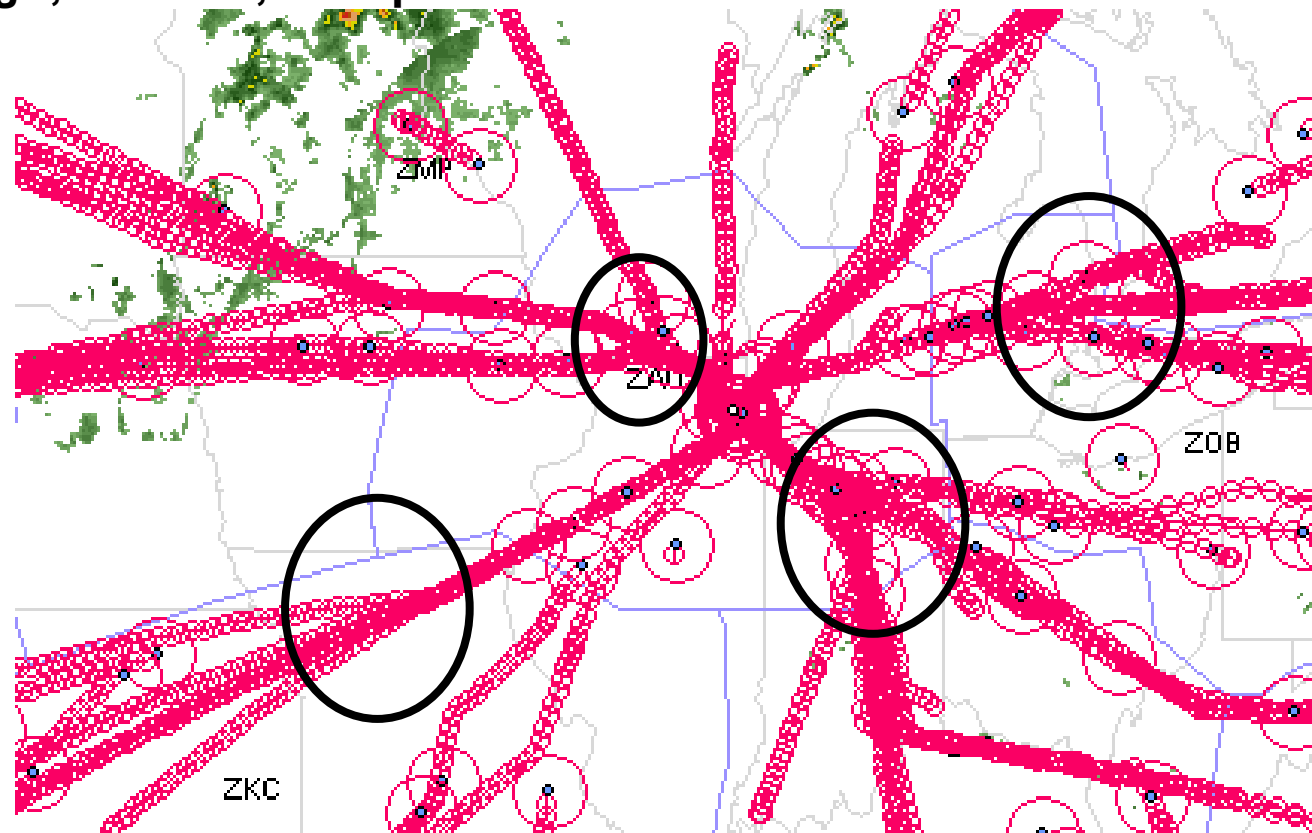

West Fixes

Flows at a Merge Point

- Observed maximum of 3 significant flows at any merge point.
- Implies number of flows to be merged is a limiting factor in complexity.
- Example: Chicago, June 11, 2:12 p.m.

ARTCC
Boundaries

Route
Flow

Flows at a Merge Point

- Generally observe 1 merge point only in a sector
- Suggests performing merges is a limiting factor in complexity.
- Example: Chicago, May 3, 8:59 p.m.

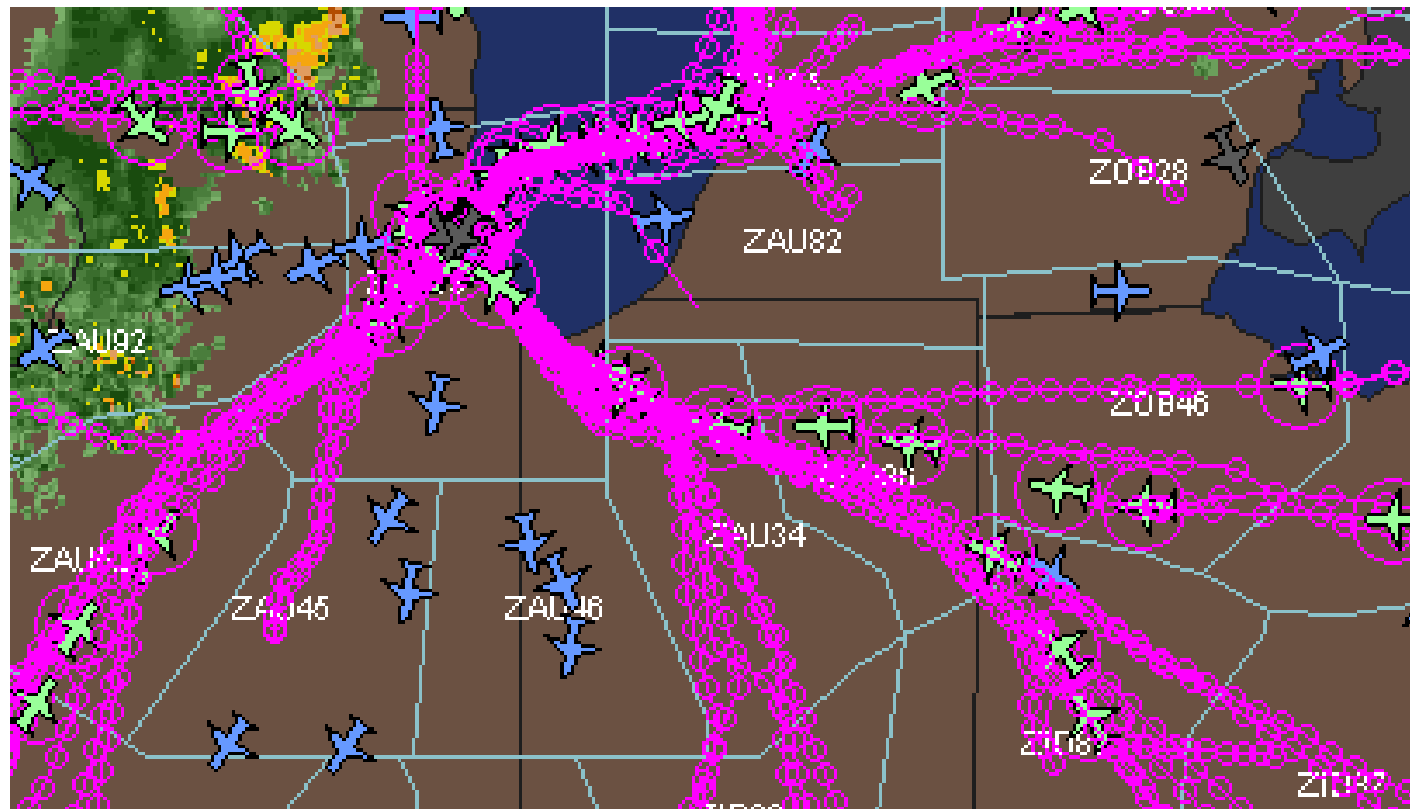

Sector
Boundaries

In-bound
ORD

In-bound's
Route
Flow

Out-bound
ORD

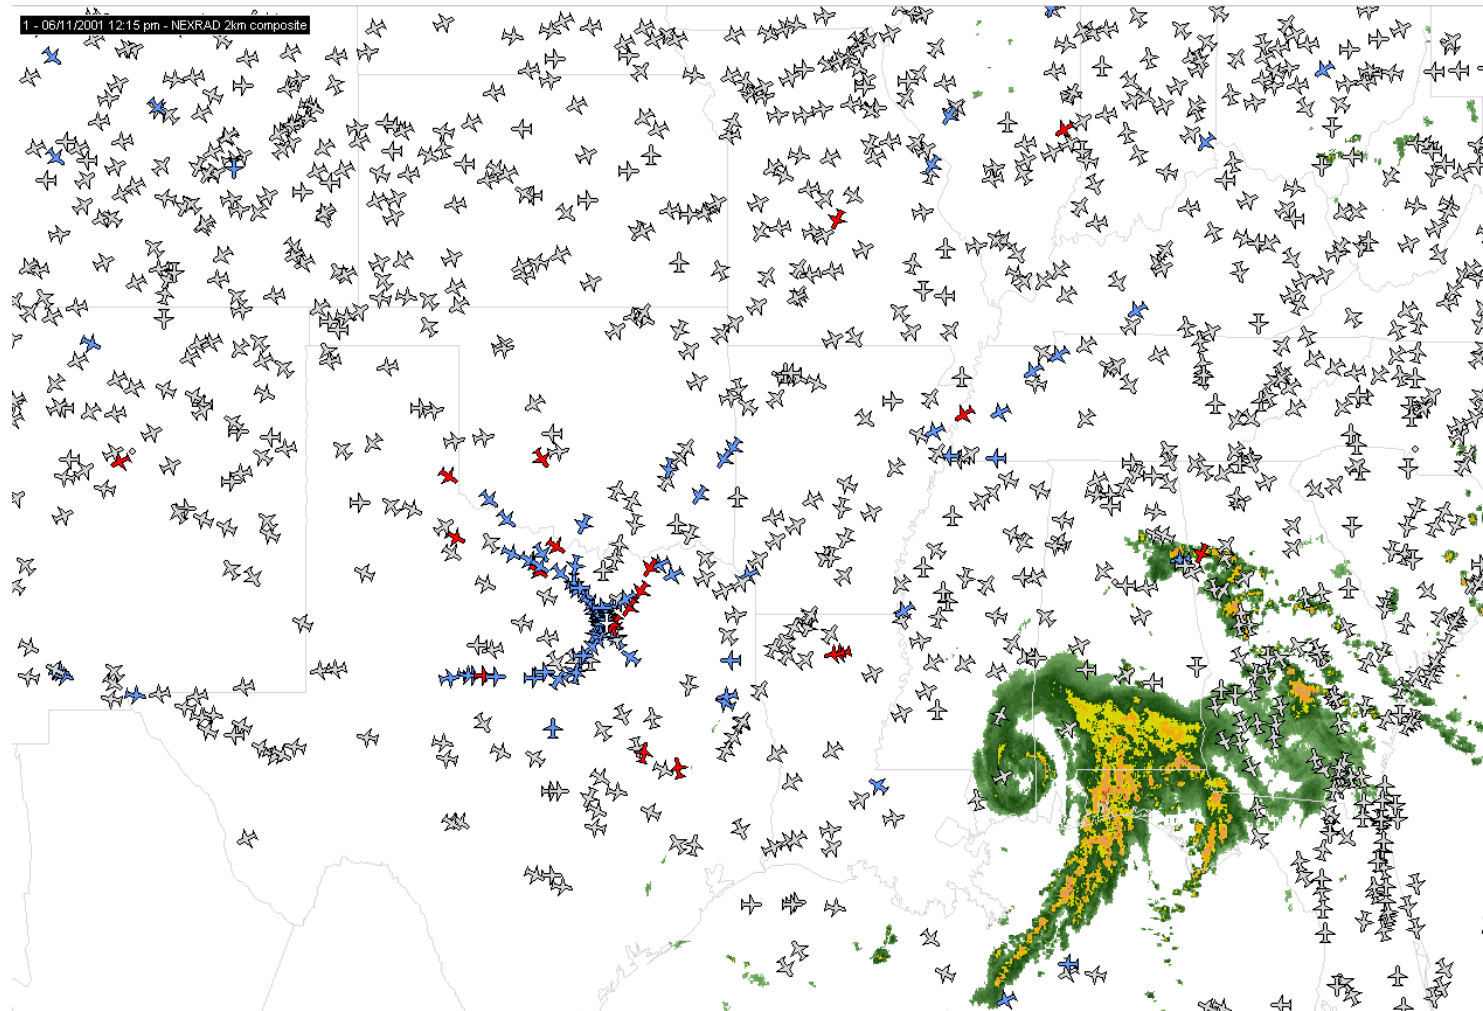

Arrival flows as part of larger system: Dallas

- June 11, 2001 12:29 p.m. 163 Aircraft In-bound (DFW/DAL)

DFW

DAL

OTHER
(> FL240)

Summarizing so far....

- **Shown there exists similar branching structure in arrival flows.**
 - ❑ Condensation points bring aircraft together to form flows
 - ❑ Flows are merged to provide final feed to an airports arrival fixes
 - ❑ Process reduces complexity of sequencing aircraft, and spreads that task across more controllers.
- **Examples of Elements Driving Complexity**
 - ❑ Special Use Airspace (San Francisco)
 - ❑ Temporal variations in demand (arrival banks in Denver)
- **Limiting Factors for Complexity:**
 - ❑ Maximum of 3 flows at a merge point
 - ❑ Only 1 merge points in a sector.

Weather, Flows, and Complexity

- **How does weather impact these flows?**
 - ❑ Rerouting
 - ◆ Chicago, May 3
 - ❑ Holding
 - ◆ Boston, April 24
 - ◆ Dallas, May 4
- **Issues for Complexity:**
 - ❑ Buffering
 - ◆ Ability to absorb aircraft should outflow be cutoff
 - ❑ Clustering
 - ◆ Result of competition between:
 - ⇒ Efficiency gained by grouping aircraft.
 - ⇒ Downstream limitations.
 - ❑ Sector Alignment to Flows

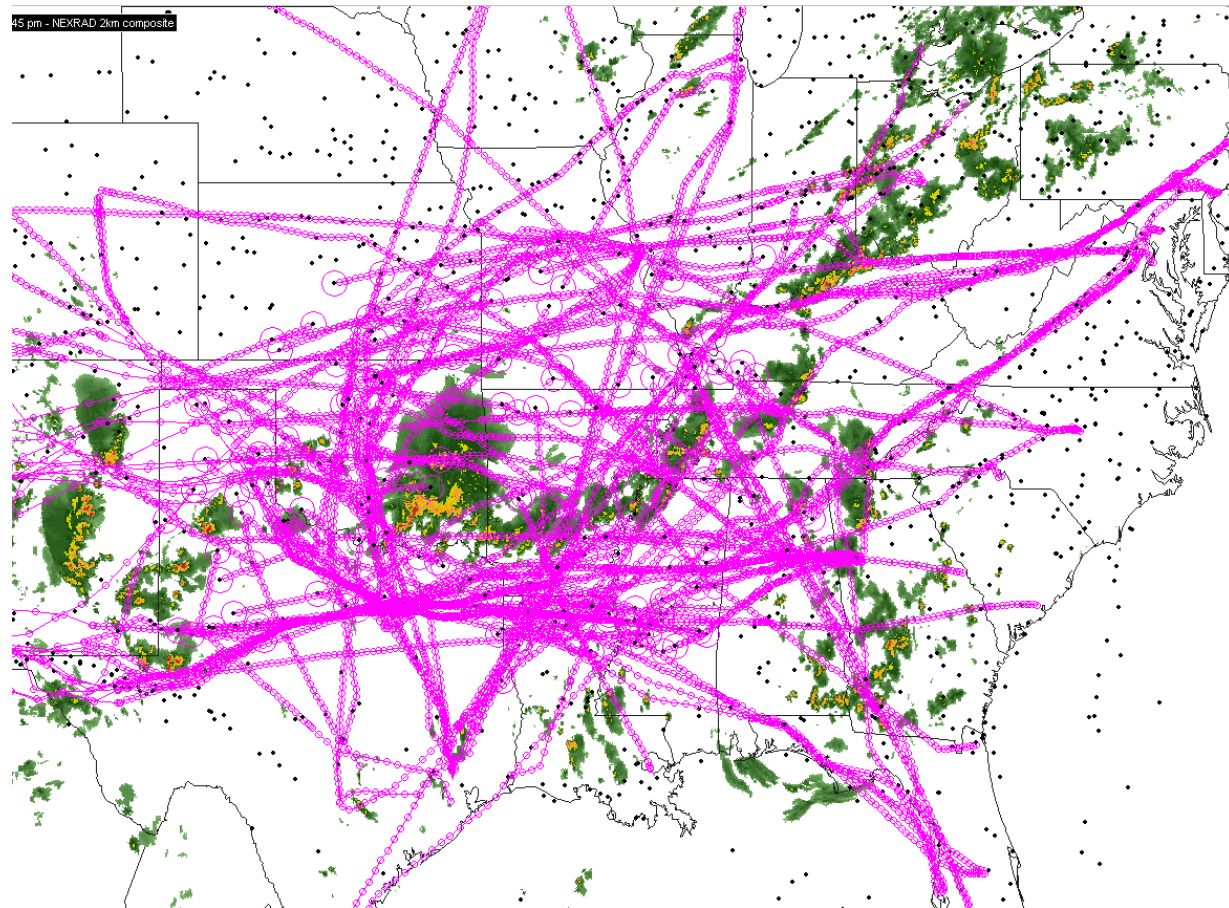

Impact of Convective Activity

- Aircraft avoiding convective weather significantly distort flows.

- May 11, 2001

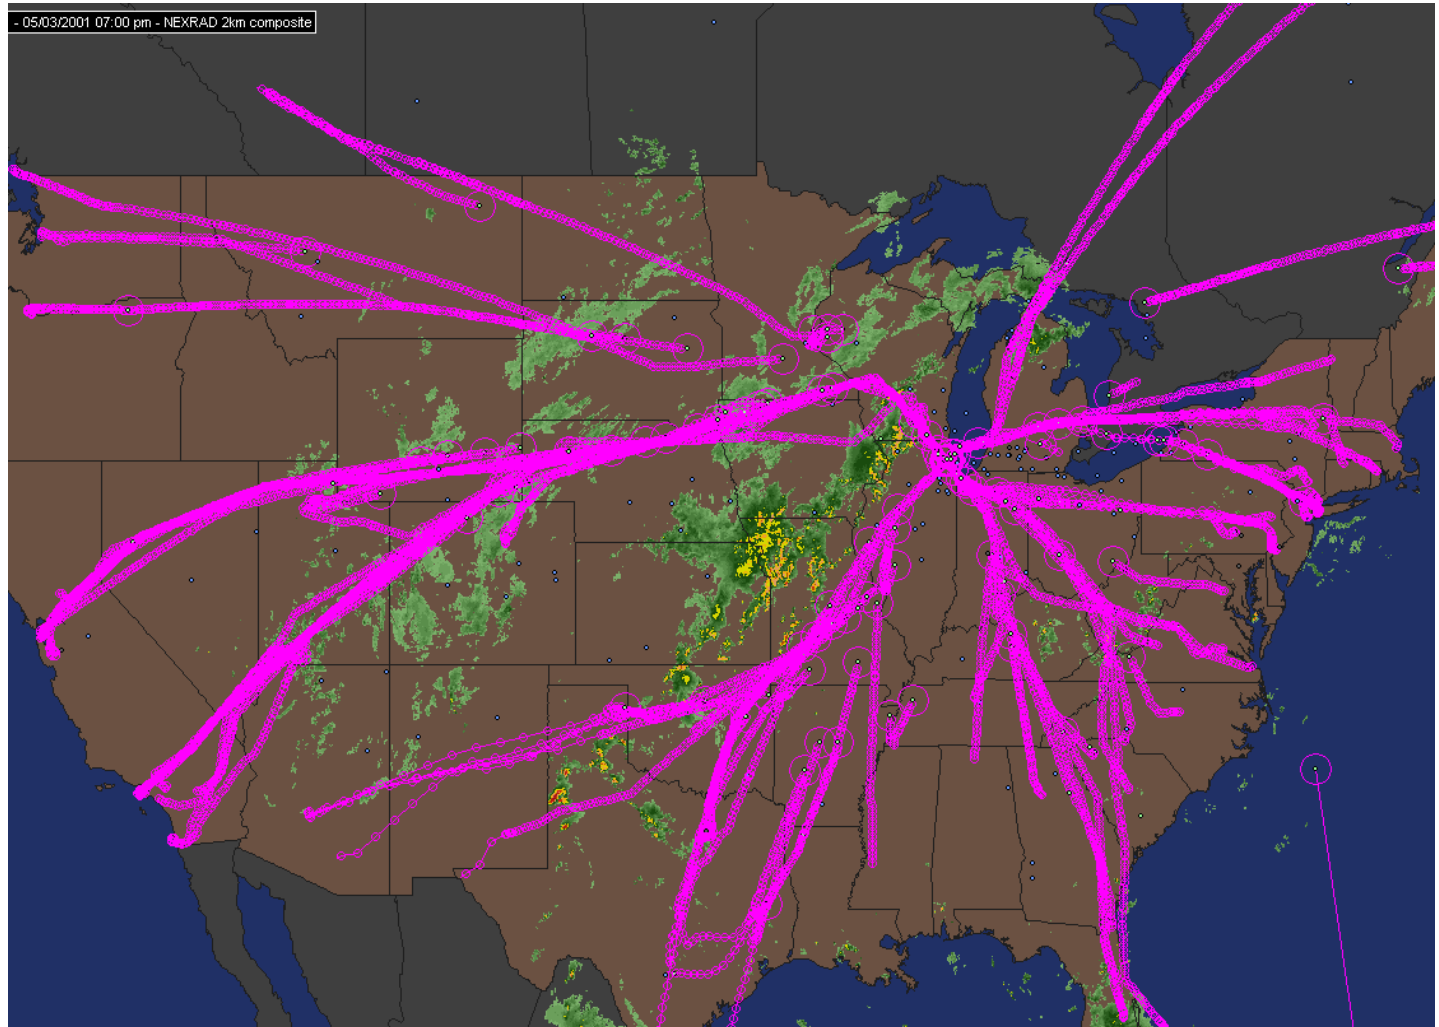

7:52 p.m.

(All Flights
above FL280)

Chicago, May 3, 7:20 pm.

- Thunderstorms about to impact NW fix.

Chicago, May 3, 8:59 pm.

- To deal with complexity associated with increased demand, diverted aircraft are integrated into existing patterns for NE fix.
- Example: Chicago, May 3, 8:59 p.m.

Illustrating the Concept of Buffering: Holding in Boston

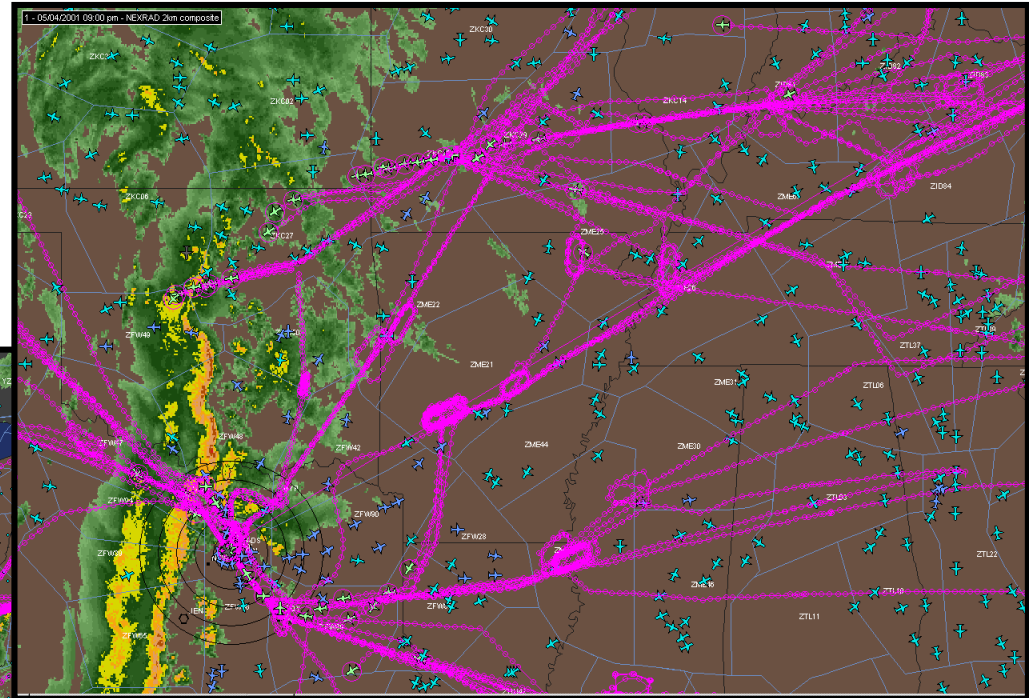

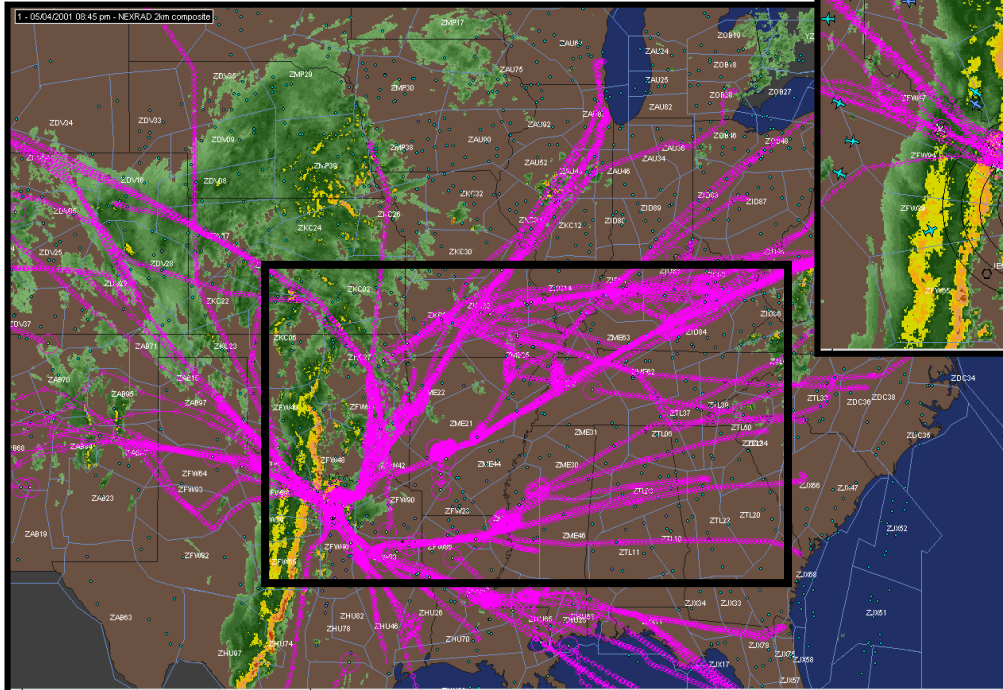

- Being forced to hold aircraft causes the buffering capacity to decrease, increasing the complexity for the controllers.
- April 24, 2001 6:33 p.m. 70 Aircraft In-bound

Backward Propagation of Holding: Dallas Fort-Worth

- May 4, 2001 9:00 p.m.

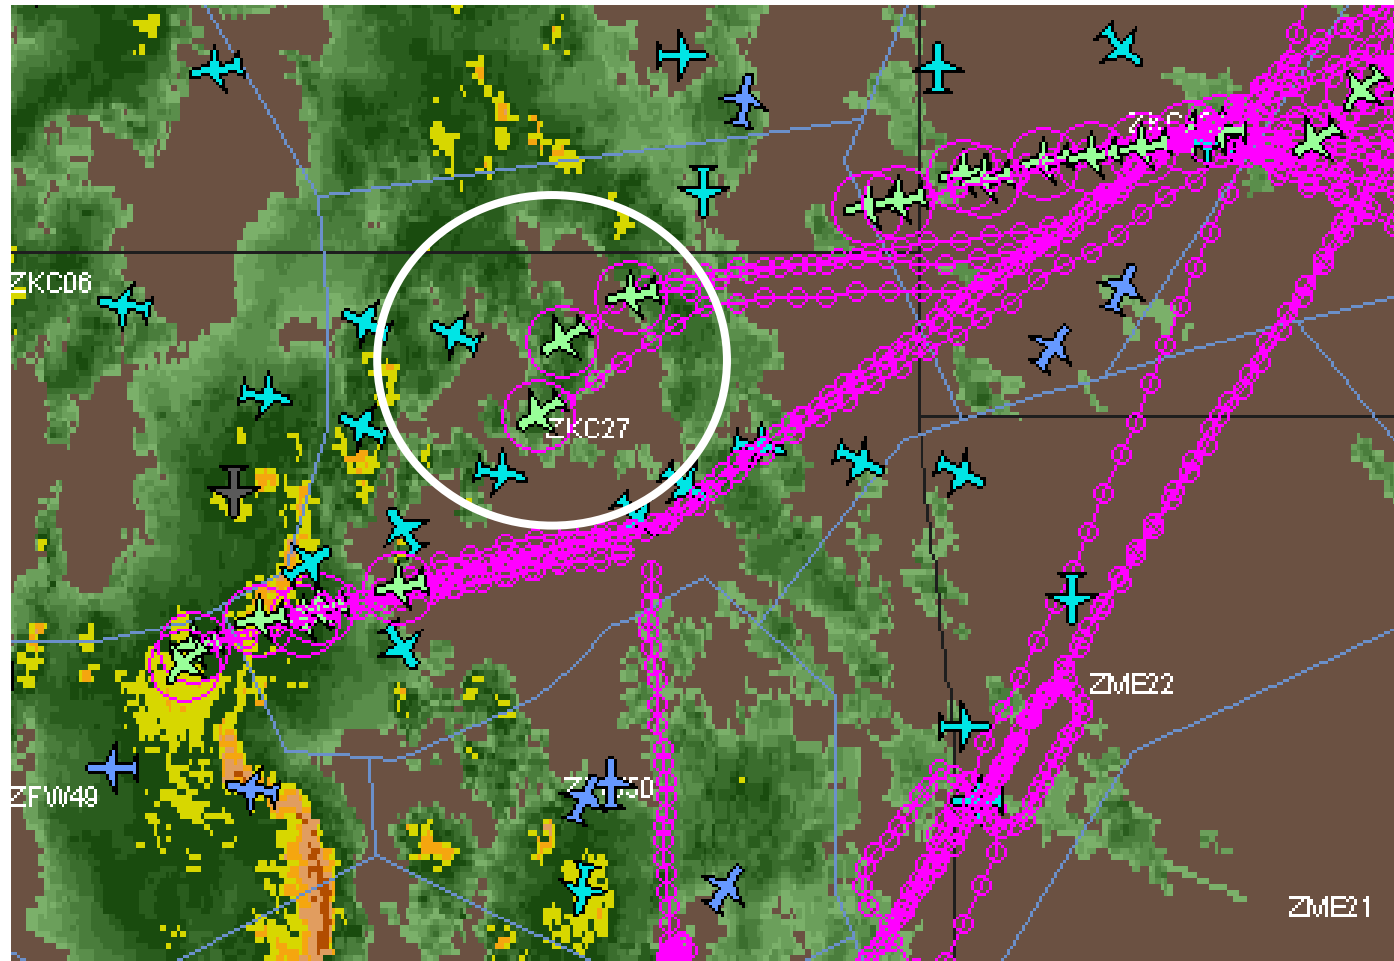

As the buffering capacity of each sector is exceeded, holding propagates back through the flows.

Clustering: Dallas Reroute

- **May 4, 2001** **9:05 p.m.**

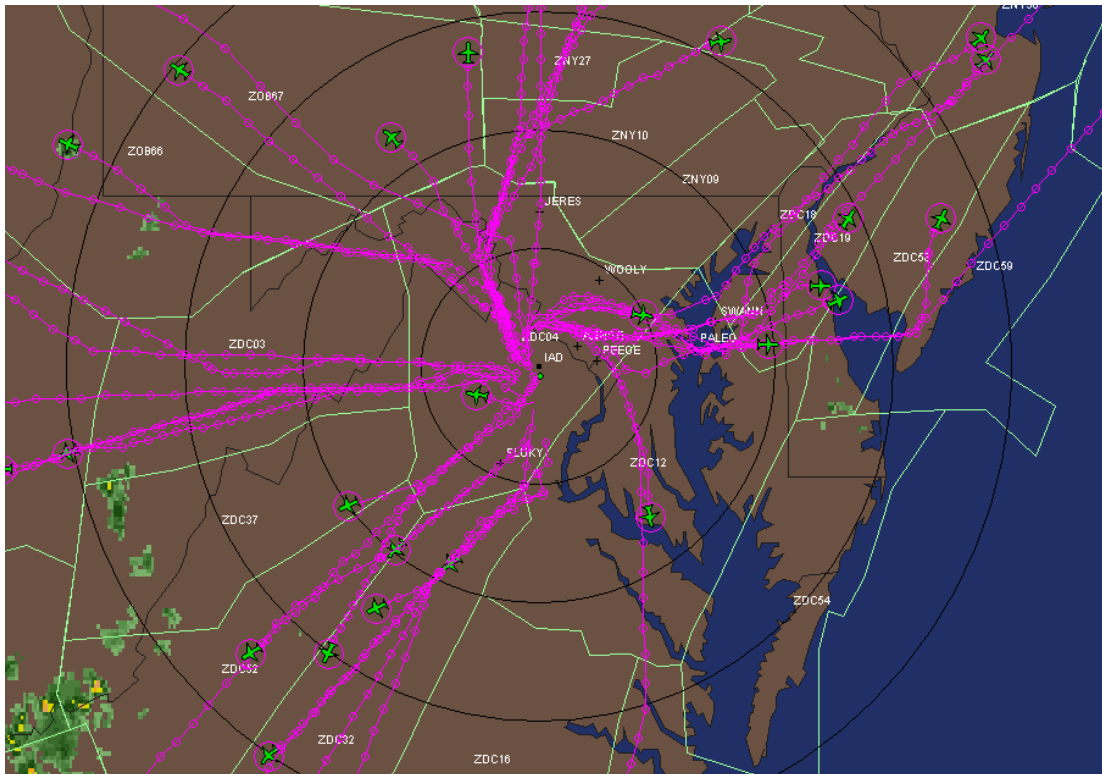

DFW In-bound

Sectors often Aligned with Major Flows Departures from Washington - Dulles

- Sectors are often designed parallel to major flows.
- Reduces ability to buffer as holding will disrupt the major flow.
- May 1, 2001 2:03 p.m. 63 Aircraft Out-bound

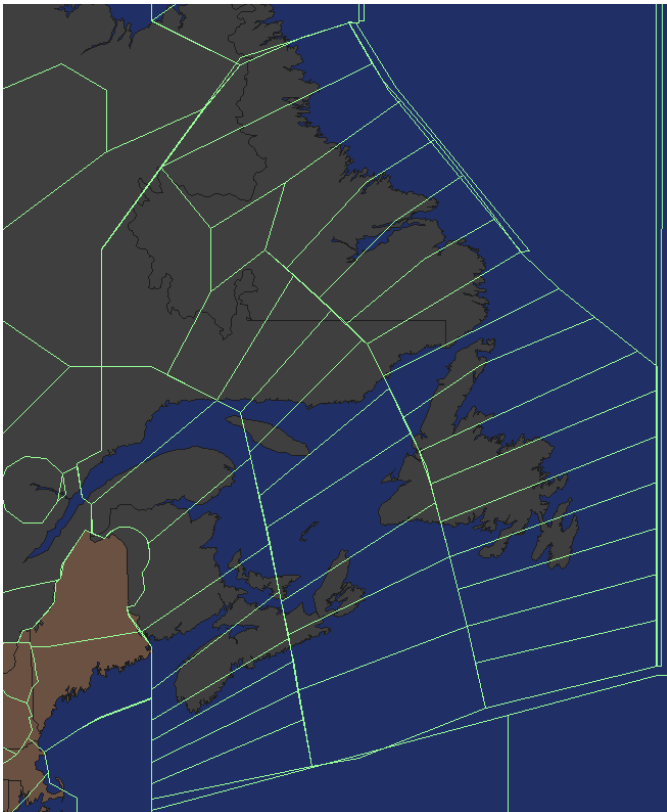

North Atlantic Tracks Transition Area

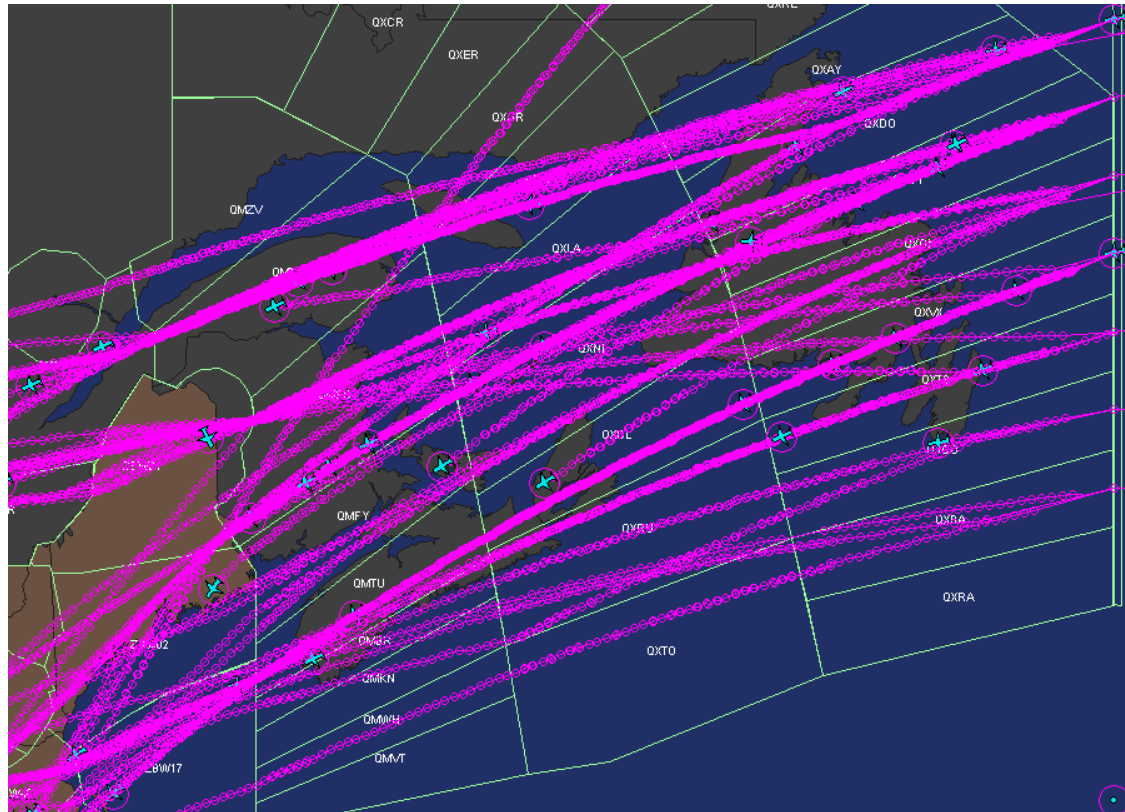

May 2001

3:18 p.m.

Sector Structure

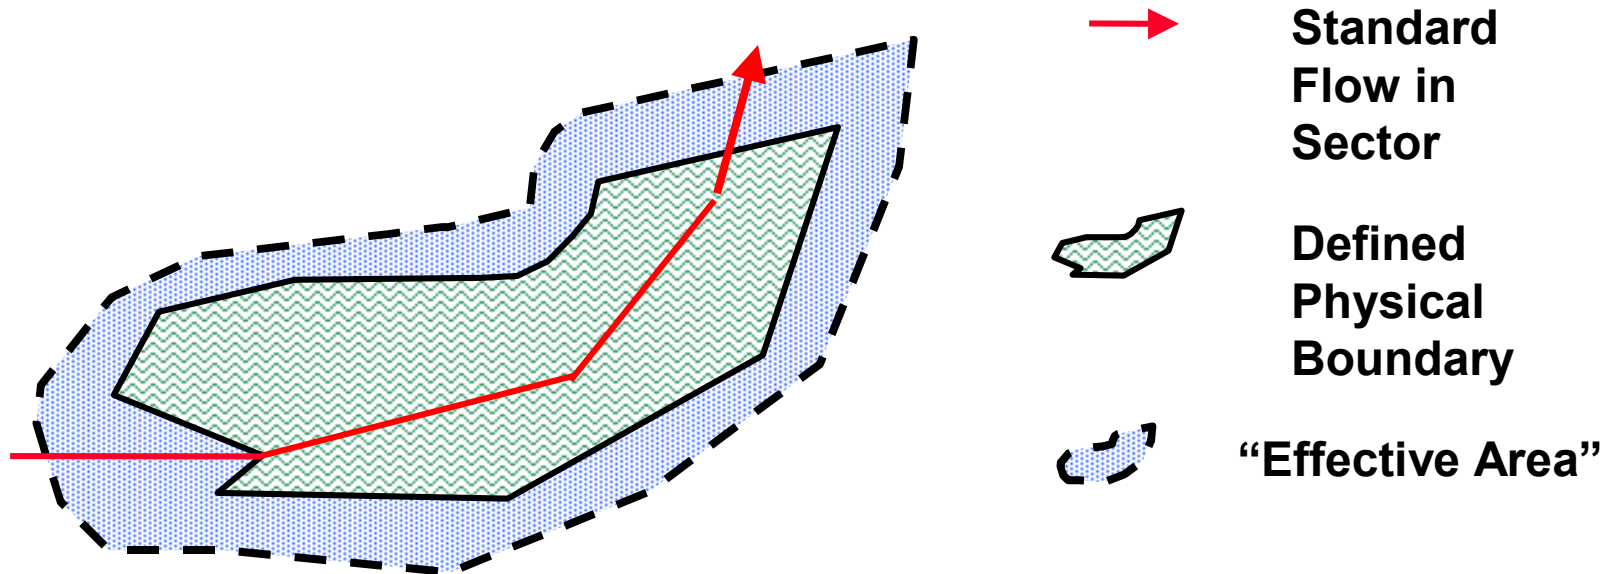

Observed Flows

Observation: The physical definition of a sector is not always appropriate.

- Identified concept of “Effective Area” of a sector
 - ❑ Example: Plymouth Position in Boston TRACON:

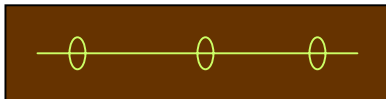

Inter-sector Potential Conflict

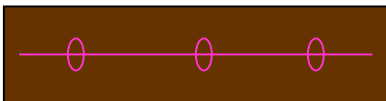

- May 3, 2000 1:08 PM
- Difficulty in detecting possible conflict 2 sectors away

High Sector
Boundaries

Flight Plan

Observed Track

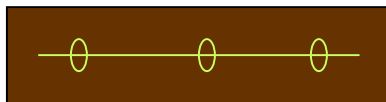

Possible conflict, May 3, 8:11 pm.

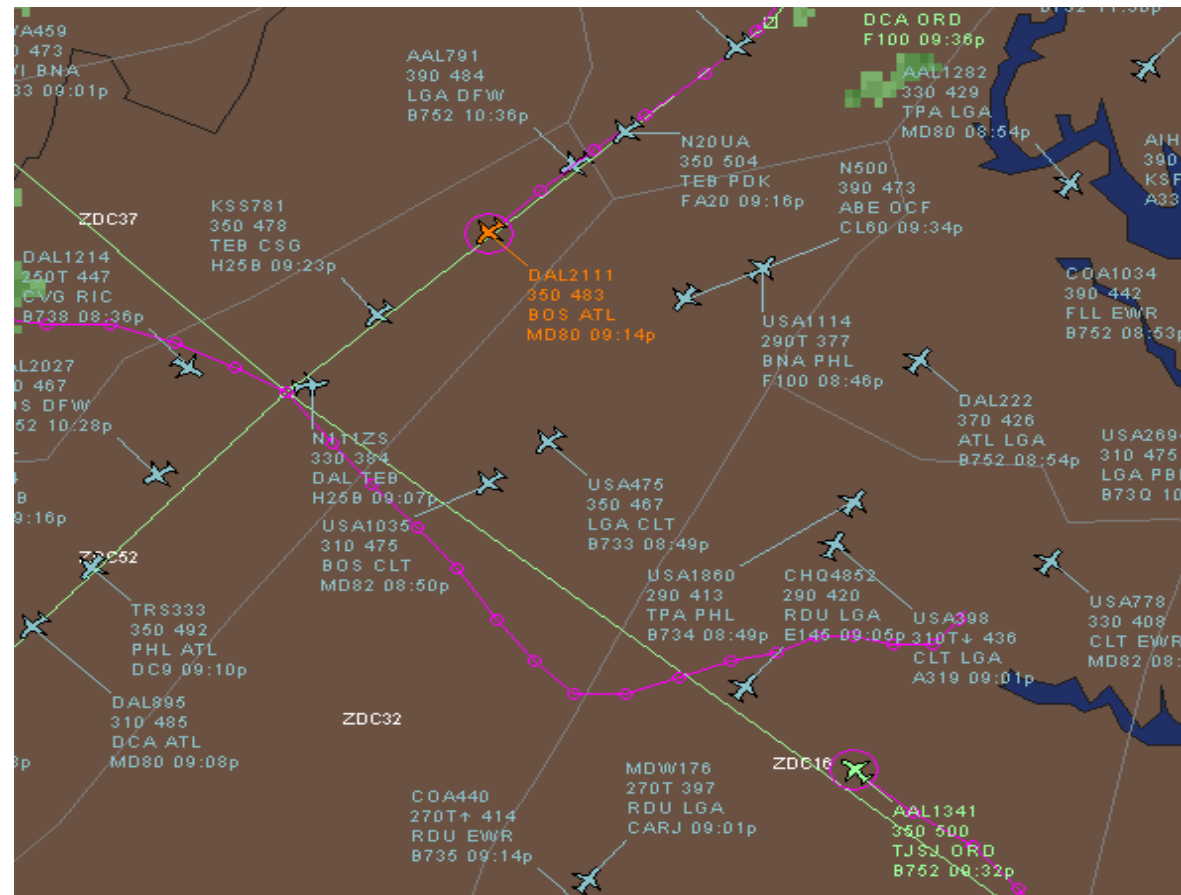

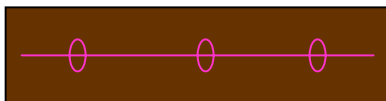

- Difficulty in detecting possible conflict 2 sectors away
- Most aircraft flowing parallel to “major-axis” of the sectors

High Sector
Boundaries

Flight Plan

Observed
Track

Summary

- **Identified Branching Structures in Arrival Patterns**
 - ☐ Aircraft are condensed into flows
 - ☐ Those flows are merged to feed airport arrival fixes
 - ☐ Process reduces complexity of sequencing aircraft, and spreads that task across more controllers.
- **Illustrated Impact on Complexity of**
 - ☐ Special Use Airspace
 - ☐ Temporal Variations in Demand
 - ☐ Weather
 - ☐ Buffering Capacity
- **Significant Observations**
 - ☐ Maximum of 3 flows at a merge point
 - ☐ Only 1 merge point in a sector

Future Work

- Pursue hypothesis that the observed structure is used to reduce complexity of the system.
- Hope to propose a metric based on a formal breakdown of the problem into the effects of:
 - ☐ Structure
 - ☐ Traffic Load
 - ☐ Operations
- **Tentative formulation:**

$$Complexity = \langle Structure \rangle \otimes \langle Traffic Load \rangle \oplus \langle Operations \rangle$$

where \otimes , \oplus are “to be determined” operators.
